This research area supports theoretical condensed matter physics with emphasis on the theory, modeling, and simulation of <u>electronic correlations</u>. A major thrust is nanoscale science, where links between the electronic optical, mechanical, and magnetic properties of nanostructures and their size, shape, topology, and composition are poorly understood. Other major research areas include <u>strongly correlated electron systems</u>, quantum transport, <u>superconductivity</u>, <u>magnetism</u>, and optics. Development of theory targeted at aiding experimental technique design and interpretation of experimental results is also emphasized. This research area supports the Computational Materials Science Network, which forms collaborating teams from diverse disciplines to address the increasing complexity of many current research issues. The research area also supports large-scale computation to <u>perform complex</u> calculations dictated by fundamental theory or to perform complex system simulations with joint funding from the Advanced Scientific Computing Research program. Capital equipment funding will be provided for items such as computer workstations and clusters.

This research area provides the fundamental knowledge for predicting the reliability and lifetime of energy use and conversion approaches and develops opportunities for next generation energy technology. Specific examples include inverse design of compound semiconductors for unprecedented solar photovoltaic conversion efficiency, solid-state approaches to improving capacity and kinetics of hydrogen storage, and ion transport mechanisms for fuel cell applications.

What are strongly correlated materials?

Conventional band picture of electrons in solid:

- screening reduces/removes effect of electron-electron repulsion
- Assume no e-e interaction, fill up single-particle bands

Strongly correlated materials: e-e interaction strongly affects properties, resulting in very interesting electronic properties

- No universal theory available
- Reduced dimensionality: quasi-2D or -1D. Reduces screening
- Unusual magnetic, charge, orbital orderings: antiferromagnetism ↑↓↑↓ often due to strong e-e interaction

Unconventional superconductivity (SC)

 $(TMTSF)_{2}X$ $T_{c}=1K SC$ κ -(BEDT-TTF)_{2}X Na_{x}CoO_{2}
SC, thermoelectric

How to approach electron correlation problem

More accurate ab initio methods:

- Hamiltonian describing electrons complex but completely specified
- One method: Diffusion Quantum Monte Carlo
- $ightarrow \Longrightarrow$ not large enough systems for many properties

Model Systems

- ▶ use simplified model Hamiltonian: Hubbard, Heisenberg, t-J, etc
- we still can't solve these exactly!
- try to give simple explanation of mechanisms

Many-body models

Ab-initio methods (DFT/etc): not presently accurate enough \rightarrow use *model* Hamiltonians. Example: Hubbard model

$$H = -t \sum_{\langle ij \rangle, \sigma} (c_{i,\sigma}^{\dagger} c_{j,\sigma} + H.c.) + U \sum_{i} n_{i,\uparrow} n_{i,\downarrow}$$

- \implies Simple model with four possible states per orbital.
- \implies Energy cost *U* for two electrons (\uparrow , \downarrow) in an orbital
- \implies t term is "tight-binding" fit to bandstructure
 - Computational challenge: # states grows exponentially
 - also: longer-range Coulomb interactions $\sum_{(i,j)} V(|r_i r_j|) n_i n_j$
 - also: electron-phonon interactions
 - also: complex crystal structures (triangular lattice)
 - also: multi-band systems

Numerical methods we use

Basic problem, quantum many-body models: exponential scaling

 $N_{states} \propto (states \ per \ orbital)^n$

There is no one method that is universally applicable.

- Exactly diagonalize Hamiltonian matrix: memory limited
- Lanczos diagonalization: Don't store the *H* matrix, lowest eigenvalue only. $N_{states} \sim 10^6$, $n \sim 20$
- Variational methods: best parameters within assumed wavefunction form
- Quantum Monte Carlo: scales well, but has serious limitations (Fermion sign problem)

Must spend time developing new methods. No commercial codes available.

Project 1: spin-fluctuation mediated Superconductivity

High-T_c cuprate superconductors: T_c up to 130 K What is a minimal model?

spin on Cu atoms:

 $\downarrow \uparrow \downarrow \uparrow$ $\uparrow \downarrow \uparrow \downarrow$ $\downarrow \uparrow \downarrow \uparrow \downarrow$

Minimal model for AFM: 2D Hubbard model

 The Hubbard model: simplified electron-electron interaction. No exact solution except in one dimension

$$H = -t \sum_{\langle ij \rangle, \sigma} (c_{i,\sigma}^{\dagger} c_{j,\sigma} + H.c.) + U \sum_{i} n_{i,\uparrow} n_{i,\downarrow}$$

Large U limit, 1 electron/orbital: antiferromagnetic Heisenberg model

$$H = J \sum_{\langle ij
angle} ec{S}_i \cdot ec{S}_j$$

 Ground state, square lattice: AFM order Suggested by P.W. Anderson (and others): doped 2D AFM = superconductor!

No exact solution or consensus yet...

Organic superconductors

- 1950's-1960's: charge transfer complexes. Goal: create organic conductors
- 1973: TTF-TCNQ: almost metallic conductivity, quasi-one dimensional
- 1979: (TMTSF)₂PF₆ (TMTSF=tetramethyl tetraselena fulvalene) first organic superconductor. Can substitute many X for PF₆. T_c ≈1 K
- Many more : BEDT-TTF, related molecules. different structures. *T_c* up to 13 K.

Organic Superconductors

Some organic SC's seem to behave like cuprates!

κ-(BEDT-TTF)₂X structure

Phase diagram

 κ -(BEDT-TTF)₂X : X is monovalent anion \implies 1 hole/two molecules \implies Back to 2D Hubbard model...

t smaller by 10, max T_c \sim 13K rather than 130K

Back to spin-fluctuation Superconductivity...

Kyung, Tremblay, PRL **97**, 046402 (2006), cluster DMFT, 4-site cluster Powell, McKenzie, PRL **98**, 027005 (2007), RVB variational ansatz

Our results: no superconductivity in this model

Necessary conditions for SC:

- U enhances SC correlations
- must have at least short-range order
- **Our work:** exact diagonalization (165 million states)

4×4 Phase diagram Clay et al, *Phys. Rev. Lett.* 101, 166403(2008)

- Pair-pair correlations decrease monotonically from U = 0
- No long range order

Followup: larger lattice (2011-2012)

Path Integral Renormalization Group (PIRG), up to 8×8 lattices

Why mean-field fails here:

AFM/metal transition: trivial increase in short-range pairing correlations

We showed: at same time, long range correlations decrease

Publications 2011-2012

Conclusion: spin-fluctuation mediated SC is a dead end...

We have suggested an alternate mechanism for SC:

Example Project 2: Layered Cobaltates

Na_xCoO₂, Li_xCoO₂, [Bi₂A₂O₄][CoO₂]_m

- 2D CoO₂ layers separated by Na, Li, etc
- potentially useful: unusually large thermoelectric coefficient
- unconventional superconductivity
- Co ion triangular lattice: "frustration" for quantum spin models
- strongly correlated: DFT bands inconsistent with experiments

Important papers:

 K. Takada et al, "Superconductivity in two-dimensional CoO₂ layers," Nature 422, 53 (2003) (>800 citations)

structure (K. Takada et al)

・ロト ・同ト ・ヨト ・ヨ

Na_xCoO₂: carrier concentration controlled by Na doping

- x = 0: Co valence = Co⁴⁺
- x = 1: Co valence = Co³⁺
 - ⇒ Simplest model: Hubbard model on triangular lattice
- Experiments:
 - Magnetic susceptibility behaves fundamentally differently for different *x*. No structural changes.
- Our theory:
 - simple Hubbard model insufficient
 - requires *nearest-neighbor* interactions:
 - $H = H_{\text{Hubbard}} + V \sum_{\langle i,j \rangle} n_i n_j$
 - many-body effect. DFT, DFT+U, DMFT, $U \rightarrow \infty$ incorrect

(I) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1))

- $\rho < 0.35$: "strongly correlated"
- $\rho > 0.35$: "weakly correlated"

Magnetic susceptibility

- Pauli paramagnetism: non-interacting electron gas
- Curie-Weiss susceptibility: associated with strong correlations, electrons avoid each other

⇒ Simple measure of "correlations": normalized *double occupancy*

$$g(
ho) = rac{\langle n_{i,\uparrow} n_{i,\downarrow}
angle}{\langle n_{i,\uparrow}
angle \langle n_{i,\downarrow}
angle}$$

Key Point: $g(\rho)$ becomes strongly ρ -dependent when V included

H. Li, R. T. Clay, S. Mazumdar, PRL 104, 216401 (2011)

$$H = -t \sum_{\langle ij \rangle, \sigma} (c^{\dagger}_{i,\sigma} c_{j,\sigma} + H.c.) + U \sum_{i} n_{i,\uparrow} n_{i,\downarrow} + V \sum_{\langle ij \rangle} n_{i} n_{j}$$

Realistic parameter regime: 6 < U/t < 14, 1 < V/t < 4

Calculate *g* for lattices $N \le 20$ (lanczos, ~20 GB largest) Result: with V > 0, behavior changes at $\rho \sim \frac{1}{3}$ exactly as in experiments

diamonds V = 2; blue triangles V = 3

Our theory

- Simple and natural description of x dependence observed in cobaltates
 - does not require ρ-dependent U or V; solution of simple Hamiltonian
 - requires many-body treatment. $U \rightarrow \infty$ limit does not give correct behavior
- Works in both 1- and 3-band models (see PRL paper)

Similarities with other strongly-correlated SC's

- Many have suggested that cobaltates are similar to cuprates (layered, strong correlations, SC in doped Mott-Hubbard, ...)
- We have pointed out even stronger similarities between the cobaltates and the organic SC's:

Phys. Status Solidi B 249, 995 (2012)

- Both have frustrated lattices (e.g. κ-(BEDT-TTF)₂X)
- Both are superconducting at only ρ = 0.5

(I) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1))

Superconducting Na_{0.35}CO₂ · yH_2O is actually $\rho = 0.5$!

Water changes the doping: some water enters as H_3O^+ , actual ρ very close to 0.5
